

User Identification Lever is the highest-priority in-scope opportunity for the flooding problem.

Decomposition

Retrieval success rate = % query understood × % correct photo reachable × % user identifies it

Out of scope

% query understood
PRODUCT OUTCOME

Did the system parse what the user meant?
(memory → intent → relevant photos)

- ✓ "John's wedding" works today
- ✗ "that rainy night we got lost"
- ✗ "the trip where everything went wrong"
- ✗ "around my birthday"

Out of scope

% correct photo reachable
PRODUCT OUTCOME

Is the correct photo actually findable?

- ✓ Photos with GPS, face tags, labels
- ✗ Old scans, indoor screenshots, no metadata → invisible to all search

In scope: top priority

% user identifies it
USER BEHAVIOR

Can the user spot the right photo?

- ✓ Results ranked well and distinct
- ✗ 150 similar beach photos: user can't tell resorts apart
- ✗ More scrolling in the results itself; no further filtering in the app.

Insight: While the Backend Engine processes queries, the biggest friction lies in the User Identification stage.
